Module 9 Lab 1: Textbook Problem 6.1, in the Cloud

Mac Mckay · CS 82A · Repo: https://github.com/raulmckay-blip/cs82a-portfolio

Overview

A pounds-to-kilograms converter, run on a Google Colab machine instead of my laptop. The function is Module 2 stuff. The point is showing the same code runs the same way in the cloud.

I uploaded this notebook to Google Colab and ran it there.

Colab URL

https://colab.research.google.com/drive/1phOs8bM26FSShaiH_vz9LH5weZl276F1?usp=sharing

Proof this ran in the cloud

My laptop is a Mac, so if this cell says Linux and finds Colab, the code ran on Google's machine, so success.

```
import os
import platform

print("Operating system:", platform.system(), platform.release())
print("Machine name:", platform.node())
try:
    import google.colab
    print("Running on Google Colab: yes")
except ImportError:
    print("Running on Google Colab: NO (this is the local kernel)")
```

```
Operating system: Linux 6.6.122+
Machine name: 0986182acff9
Running on Google Colab: yes
```

Problem 6.1: Pounds to kilograms

1 lb = 0.453592 kg

```
def convert_lbs_to_kgs(lbs):
    return lbs * 0.453592
```

Testing it on three values

One of them is my own weight.

```
# Test 1: My own weight
print("My weight in kg:", round(convert_lbs_to_kgs(180),2))

# Test 2: A lighter value
print("1 lbs in kg:", round(convert_lbs_to_kgs(1),2))

# Test 3: A heavier value
print("125,000 lbs in kg:", round(convert_lbs_to_kgs(125000),2))
```

```
My weight in kg: 81.65
1 lbs in kg: 0.45
125,000 lbs in kg: 56699.0
```

AI use

AI helped set up the template and the cloud-check cell. The function and the calls are my own work.
